Vectors

We will be using vectors and matrices to store and manipulate data.

Definition: A vector $\vec{\mathbf{v}}$ is a column of numbers. Use bold faced letters or vector signs to distinguish vectors from other variables.

We refer to the **entries** of a vector by using subscripts.

The **length** of a vector is the number of entries it has. (normally n)

Example.
$$\vec{\mathbf{v}} = \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 1 \\ 2 \\ 3 \end{bmatrix} = \begin{bmatrix} 1 & 2 & 3 \end{bmatrix}^T$$
.

Example. Use a vector to represent the age distribution of a population: let F_i be the number of females with ages in the interval [5i, 5(i+1)). We can represent $\vec{\mathbf{F}}$ the total female population by the vector $\vec{\mathbf{F}}$. The females from 0 up to 5 are counted in F_0 ; those from 5 up to 10 are counted in F_1 , etc.

Matrices

Definition: A matrix A is a two-dimensional array of numbers.

A matrix with m rows and n columns is called an $m \times n$ matrix.

* Row by column — Row by column — Row by column *

Note: A vector can be thought of as an $n \times 1$ matrix.

Matrices are denoted by a capital letter. Entries are lower case and have two subscripts, the corresponding row and column.

Example. A generic 2×3 matrix has the form $A = \begin{bmatrix} a_{1,1} & a_{1,2} & a_{1,3} \\ a_{2,1} & a_{2,2} & a_{2,3} \end{bmatrix}$.

Definition: The matrix $B = \begin{bmatrix} 30 & 50 \\ 100 & 250 \end{bmatrix}$ is a **square matrix**

because it has the same number of rows as columns.

Matrices

Example. We will sometimes interpret a matrix as a transition matrix.

In this case, the matrix is square (say $n \times n$), where the n rows and n columns correspond to certain **states** (situations).

An entry $a_{i,j}$ represents transitioning from state j to state i.

Example. In our population example, suppose we want to model people getting older, transitioning from one state (age group) to the next. We would set up a transition matrix such as:

FROM state:

0	0	0	0	0	
1	0	0	0	0	
0	1	0	0	0	
0	0	1	0	0	
0	0	0	1	0	
	0 1 0 0 0	0 0 1 0 0 1 0 0 0 0	0 0 0 1 0 0 0 1 0 0 0 1 0 0 0	1 0 0 0 0 1 0 0	$egin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \end{bmatrix}$

because everyone in the first age group will move to the second age group $(a_{2,1})$, everyone in state 2 will move to state 3 $(a_{3,2})$, etc.

The power of matrices arises in their multiplication.

Given two matrices, A of size $m \times k$ and B of size $l \times n$, we can find the product AB if and only if k equals l.

Let A be an $m \times k$ matrix and B, $k \times n$. Then AB is of size $m \times n$.

To calculate the entries of AB, remember: "Row by column":

$$\begin{bmatrix} 1 & 4 \\ -1 & 0 \end{bmatrix} \begin{bmatrix} 2 & 0 & 6 \\ -4 & 1 & 2 \end{bmatrix} = \begin{bmatrix} \bigcirc & \bigcirc & \bigcirc \\ \bigcirc & \bigcirc & \bigcirc \end{bmatrix}$$

When we write A^2 , this means AA; A^3 means AAA, etc.

The power of transition matrices

Example. Modeling a changing population using a matrix model.

Let us choose a size of age interval Δ =5 years ("Delta"), and divide the female population into states:

age distribution vector:

State 0: ages
$$[0,5)$$
 with $F_0 = 150$ females

State 1: ages $[5,10)$ with $F_1 = 200$ females

State 2: ages $[10,15)$ with $F_2 = 180$ females

State 3: ages $[15,20)$ with $F_3 = 120$ females

State 4: ages $[20,25)$ with $F_4 = 60$ females

 $\begin{bmatrix} 150 \\ 200 \\ 180 \\ 120 \\ 60 \end{bmatrix}$

Using a transition matrix, we can determine the population in Δ years:

$$A \cdot \vec{\mathbf{F}} = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \end{bmatrix}^{1} \begin{bmatrix} 150 \\ 200 \\ 180 \\ 120 \\ 60 \end{bmatrix} = \begin{bmatrix} 0 \\ 150 \\ 200 \\ 180 \\ 120 \end{bmatrix}$$

Leslie Matrices

The transition matrix in the previous example is not entirely realistic, because people die and are born

To take death into account, modify:

To take birth into account, modify: (i females!)

The resulting transition matrix is called a **Leslie matrix**:

Let m_i be the average number of females that women in state i bear. Let p_i be the fraction of women in state i that survive to state i + 1.

then
$$\begin{bmatrix} F_0(t+\Delta) \\ F_1(t+\Delta) \\ F_2(t+\Delta) \\ \vdots \\ F_{n-1}(t+\Delta) \end{bmatrix} = \begin{bmatrix} m_0 & m_1 & m_2 & \cdots & m_{n-1} \\ p_0 & 0 & 0 & \cdots & 0 \\ 0 & p_1 & 0 & \cdots & 0 \\ \vdots & & \ddots & & \vdots \\ 0 & \cdots & 0 & p_{n-2} & 0 \end{bmatrix} \begin{bmatrix} F_0(t) \\ F_1(t) \\ F_2(t) \\ \vdots \\ F_{n-1}(t) \end{bmatrix}$$
 $\vec{\mathbf{F}}(t+\Delta) = M \cdot \vec{\mathbf{F}}(t)$

Leslie Matrices

Example. An animal population example (p. 47) The population in three age groups, $F_0 = 80$, $F_1 = 40$, and $F_2 = 20$.

Suppose that as Δ time passes, everyone in state 2 dies, and one quarter of everyone else dies. Also suppose that the age-specific maternity rates are $m_0=0$, $m_1=1$, and $m_2=2$. Determine the Leslie matrix and the population distributions at times Δ and 2Δ .

$$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 80 \\ 40 \\ 20 \end{bmatrix} = \begin{bmatrix} \end{bmatrix} = \vec{\mathbf{F}}(\Delta)$$

$$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \end{bmatrix} = \begin{bmatrix} \end{bmatrix} = \vec{\mathbf{F}}(2\Delta)$$

Matrices and Vectors in Mathematica

We can use Mathematica to do these calculations. (See Tutorial 5.)

▶ Matrices are defined as lists of row vectors.

```
matrix = \{\{0, 1, 2\}, \{.75, 0, 0\}, \{0, .75, 0\}\}\
vector = \{\{80\}, \{40\}, \{20\}\}\
```

- Multiply matrices by using a period (.) matrix.vector
- ► Find powers of matrices using MatrixPower, not ^ MatrixPower[matrix, 2]
- ➤ So, to find animal population over time, use the code: Table[, {i, 0, 10}]
