Completeness for Isomorphisms

Theorem (Hirschfeldt-Khoussainov-Shore-Slinko 2002)

For every automorphically nontrivial, countable structure $\mathcal{A}$, there exists a countable graph $G$ which has the same spectrum as $\mathcal{A}$, the same $d$-computable dimension as $\mathcal{A}$ (for each $d$), and the same categoricity properties as $\mathcal{A}$ under expansion by a constant, and which realizes every $\text{DgSp}_{\mathcal{A}}(R)$ (for every relation $R$ on $\mathcal{A}$) as the spectrum of some relation on $G$.

Moreover, this holds not only of graphs, but also of partial orderings, lattices, rings, integral domains of arbitrary characteristic, commutative semigroups, and 2-step nilpotent groups.

Given $\mathcal{A}$, they built a graph $G = \mathcal{G}(\mathcal{A})$ such that the isomorphisms from $\mathcal{A}$ onto any $\mathcal{B}$ correspond bijectively with the isomorphisms from $\mathcal{G}(\mathcal{A})$ onto $\mathcal{G}(\mathcal{B})$, by a map $f \mapsto \mathcal{G}(f)$ which preserves the Turing degree of $f$. 

Russell Miller (CUNY)
Incompleteness for Isomorphisms

The following classes of structures are known not to be complete in this way, by results of Richter, Dzgoev and Goncharov, Remmel, and many others:

- linear orders
- Boolean algebras
- trees (as partial orders, or under the meet function)
- abelian groups
- real closed fields
- algebraically closed fields
- fields of finite transcendence degree over $\mathbb{Q}$.
From Graphs to Fields

**Theorem (MPPSS)**

For every countable graph \( G \), there exists a countable field \( \mathcal{F}(G) \) with the same computable-model-theoretic properties as \( G \), as in the HKSS theorem. Indeed, \( \mathcal{F} \) may be viewed as an effective, fully faithful functor from the category of countable graphs (under monomorphisms) into the class of fields, with an effective inverse functor (on its image).

Full faithfulness means that each field homomorphism \( \mathcal{F}(G) \to \mathcal{F}(G') \) comes from a unique monomorphism \( G \to G' \). Isomorphisms \( g : G \to G' \) will map to isomorphisms \( \mathcal{F}(g) : \mathcal{F}(G) \to \mathcal{F}(G') \).

We do not claim that every \( F' \cong \mathcal{F}(G) \) lies in the image of \( \mathcal{F} \). This situation will require attention.
Construction of $\mathcal{F}(G)$

We use two curves $X$ and $Y$, defined by integer polynomials:

$$X : p(u, v) = u^4 + 16uv^3 + 10v^4 + 16v - 4 = 0$$

$$Y : q(T, x, y) = x^4 + y^4 + 1 + T(x^4 + xy^3 + y + 1) = 0$$

Let $G = (\omega, E)$ be a graph. Set $K = \mathbb{Q}(\prod_{i \in \omega} X)$ to be the field generated by elements $u_0 < v_0 < u_1 < v_1, \ldots$, with $\{u_i : i \in \omega\}$ algebraically independent over $\mathbb{Q}$, and with $p(u_i, v_i) = 0$ for every $i$. The element $u_i$ in $K \subseteq \mathcal{F}(G)$ will represent the node $i$ in $G$.

Next, adjoin to $K$ elements $x_{ij}$ and $y_{ij}$ for all $i > j$, with $\{x_{ij} : i > j\}$ algebraically independent over $K$, and with

$$q(u_i u_j, x_{ij}, y_{ij}) = 0 \text{ if } (i, j) \in E$$

$$q(u_i + u_j, x_{ij}, y_{ij}) = 0 \text{ if } (i, j) \notin E.$$

We write $Y_t$ for the curve defined by $q(t, x, y) = 0$ over $\mathbb{Q}(t)$. So the process above adjoins the function field of either $Y_{u_i u_j}$ or $Y_{u_i + u_j}$, for each $i > j$. $\mathcal{F}(G)$ is the extension of $K$ generated by all $x_{ij}$ and $y_{ij}$.
Reconstructing $G$ From $\mathcal{F}(G)$

Lemma

Let $G = (\omega, E)$ be a graph, and build $\mathcal{F}(G)$ as above. Then:

(i) $X(\mathcal{F}(G)) = \{(u_i, v_i) : i \in \omega\}$.

(ii) If $(i, j) \in E$, then $Y_{u_iu_j}(\mathcal{F}(G)) = \{(x_{ij}, y_{ij})\}$ and $Y_{u_i+u_j}(\mathcal{F}(G)) = \emptyset$.

(iii) If $(i, j) \notin E$, then $Y_{u_iu_j}(\mathcal{F}(G)) = \emptyset$ and $Y_{u_i+u_j}(\mathcal{F}(G)) = \{(x_{ij}, y_{ij})\}$.

This is the heart of the proof. (i) says that $p(u, v) = 0$ has no solutions in $\mathcal{F}(G)$ except the ones we put there, so we can enumerate

$$\{u_i : i \in \omega\} = \{u \in \mathcal{F}(G) : (\exists v \in \mathcal{F}(G)) p(u, v) = 0\}.$$

Similarly, (ii) and (iii) say that the equations $q(u_iu_j, x, y) = 0$ and $q(u_i + u_j, x, y) = 0$ have no unintended solutions in $\mathcal{F}(G)$. So, given $i$ and $j$, we can determine from $\mathcal{F}(G)$ whether $(i, j) \in E$: search for a solution to either $q(u_iu_j, x, y) = 0$ or $q(u_i + u_j, x, y) = 0$. 

Russell Miller (CUNY)
Lemma 0.2. Let $G = (V, E)$ be a graph. Let $z_{ij}, y_{ij} \in \mathcal{F}(G)$ correspond to the rational functions $x, y$ on $Z_{ij}$. 

(i) We have $X(\mathcal{F}(G)) = \{(u, v) : i \in V\}$.
(ii) If $(i, j) \in E$, then $Y_{\mathcal{F}(G)} = \{(x, y_{ij})\}$ and $Y_{\mathcal{F}(G)} = \emptyset$.
(iii) If $(i, j) \notin E$, then $Y_{\mathcal{F}(G)} = \emptyset$ and $Y_{\mathcal{F}(G)} = \{(x, y_{ij})\}$.

Proof. By definition, $\mathcal{F}(G)$ is the direct limit of $F(Z)$, where $Z$ ranges over finite products of the $Z_{ij}$. Thus, by Lemma 0.4, each point in $X(\mathcal{F}(G))$ corresponds to a rational map from some $Z$ to $X$. By Lemmas 0.6 and 0.2 every such rational map is constant. In other words, $X(\mathcal{F}(G)) = X(F)$.

Similarly, by Lemma 0.4, each point in $Y(F)$ corresponds to a rational map from some finite power of $X$ to $Y$. By (5), the rational map is nonconstant. By Lemmas 0.6 and 0.2 it is the $i$th projection for some $i$. The corresponding point in $X(F)$ is $(u, v_i)$.

Lemma 0.3. If $V$ and $W$ are varieties over a field $k$, and $W$ is integral, then $V(k(W))$ is an injection with the set of rational maps $W \rightarrow V$.

Proof. The description of a point in $V(k(W))$ involves only finitely many elements of $k(W)$, and there is a dense open subvariety $U \subseteq W$ on which they are all regular.

Lemma 0.5. Let $k$ be a field of characteristic 0. Let $C$ and $D$ be geometrically integral curves over $k$ such that $g_C = g_D > 1$. Every nonconstant rational map $C \rightarrow D$ is a birational map.

Proof. This is a well known consequence of Hurwitz’s formula. 

Lemma 0.6. Let $V_1, \ldots, V_n$ be geometrically integral varieties over a field $k$. Let $C$ be a geometrically integral curve over $k$ such that $g_C > 1$. Then each rational map $V_1 \times \cdots \times V_n \rightarrow C$ factors through the projection $V_1 \times \cdots \times V_n \rightarrow V_i$ for at least one $i$.

Proof. By induction, we may assume that $n = 2$. We may assume that $k$ is algebraically closed. A rational map $\phi : V_1 \times V_2 \rightarrow C$ may be viewed as an algebraic family of rational maps $V_1 \rightarrow C$ parametrized by an (open) subvariety of $V_2$. But the de Franchis-Seventheorem [San60, Théorème 2] implies that there are no nonconstant algebraic families of nonconstant rational maps $V_1 \rightarrow C$. Thus either the rational maps in the family are all the same, in which case $\phi$ factors through the first projection, or each rational map in the family is constant, in which case $\phi$ factors through the second projection.

References

Suppose \( g : G \rightarrow G' \) is a graph monomorphism. The map
\[ f = \mathcal{F}(g) : \mathcal{F}(G) \rightarrow \mathcal{F}(G') \]
uses a \( g \)-oracle to map
\[ (u_i, v_i) \mapsto (u'_{g(i)}, v'_{g(i)}) \quad \text{and} \quad (x_{ij}, y_{ij}) \mapsto (x'_{g(i)g(j)}, y'_{g(i)g(j)}). \]

\((\mathcal{F}(G)\) is built by a tightly defined process, so all these elements are known.) With
\[ q(u_iu_j, x_{ij}, y_{ij}) = 0 \text{ in } \mathcal{F}(G) \iff (i, j) \in E \]
\[ \iff (g(i), g(j)) \in E' \]
\[ \iff q(u'_{g(i)u'_{g(j)}}, x'_{g(i)g(j)}, y'_{g(i)g(j)}) = 0 \text{ in } \mathcal{F}(G'), \]
and likewise for \( u_i + u_j \), this \( f \) extends to a field homomorphism, using oracles for \( \mathcal{F}(G) \) \((\leq_T G)\) and \( \mathcal{F}(G') \) \((\leq_T G')\). So \( f \leq_T g \oplus G \oplus G' \).

Finally, \( g \) is an isomorphism iff \( \mathcal{F}(g) \) is.
Suppose $f : \mathcal{F}(G) \rightarrow \mathcal{F}(G')$ is an isomorphism. We identify $u_0, u_1, \ldots$ in $\mathcal{F}(G)$ and $u'_0, u'_1 \ldots$ in $\mathcal{F}(G')$.

Now $f$ must map each $(u_i, v_i)$ to some $(u'_k, v'_k)$. Define $g = \mathcal{F}^{-1}(f) : G \rightarrow G'$ by $g(i) = k$. With $f$ an isomorphism, this $g$ is onto $G'$ and preserves the edge relations in $G$ and $G'$:

$$
(i, j) \in E \iff (\exists x, y \in \mathcal{F}(G) \ q(u_i u_j, x, y) = 0
$$
$$
\iff (\exists x', y' \in \mathcal{F}(G') \ q(u'_g(i) u'_g(j), x', y') = 0
$$
$$
\iff (g(i), g(j)) \in E'.
$$

Indeed $g \leq_T f$, with no oracle needed for $G$, $\mathcal{F}(G)$, $G'$, or $\mathcal{F}(G')$. Moreover, $\mathcal{F}(g) = f$, and so $f \leq_T g \oplus G \oplus G'$. 

Russell Miller (CUNY)
Fields Which $F$ Missed

Fix $G$ and suppose $f : F \cong \mathcal{F}(G)$. With an $F$-oracle, we can enumerate $X(F)$, thus listing out $u_0, u_1, \ldots$ in $F$. Define a graph $G'$ on $\omega$ by

$$(i, j) \in E' \iff (\exists x, y \in F) \ q(u_i u_j, x, y) = 0.$$ 

Since $F \cong \mathcal{F}(G)$, we have $(i, j) \notin E'$ iff $(\exists x, y \in F) \ q(u_i + u_j, x, y) = 0$, so $E'$ is $\Delta^F_1$, and $G' \leq_T F$.

Therefore $F' := \mathcal{F}(G') \leq_T F$. Moreover, $u_i \mapsto u'_i$ and $v_i \mapsto v'_i$ extends to an isomorphism $f' : F \to F'$, with

$$f' \leq_T F \oplus F' \equiv F \oplus \mathcal{F}(G') \leq_T F \oplus G' \leq_T F.$$ 

Finally, $f' \circ f^{-1} : \mathcal{F}(G) \to \mathcal{F}(G')$ yields an isomorphism $g : G \to G'$, by full faithfulness.
Fields Which Missed

Fix $G$ and suppose $f : F \cong \mathbb{F}(G)$. With an $F$-oracle, we can enumerate $X(F)$, thus listing out $u_0, u_1, \ldots$ in $F$. Define a graph $G'$ on $\omega$ by

$$(i, j) \in E' \iff (\exists x, y \in F) \ q(u_i u_j, x, y) = 0.$$  

Since $F \cong \mathbb{F}(G)$, we have $(i, j) \notin E'$ iff $(\exists x, y \in F) \ q(u_i + u_j, x, y) = 0$, so $E'$ is $\Delta^F_1$, and $G' \leq_T F$.

Therefore $F' := \mathbb{F}(G') \leq_T F$. Moreover, $u_i \mapsto u'_i$ and $v_i \mapsto v'_i$ extends to an isomorphism $f' : F \to F'$, with

$$f' \leq_T F \oplus F' \cong F \oplus \mathbb{F}(G') \leq_T F \oplus G' \leq_T F.$$  

Finally, $f' \circ f^{-1} : \mathbb{F}(G) \to \mathbb{F}(G')$ yields an isomorphism $g : G \to G'$, by full faithfulness.

Lemma

Every $F$ isomorphic to $\mathbb{F}(G)$ has an $F$-computable isomorphism onto some $\mathbb{F}(G')$, for some $F$-computable $G' \cong G$.  

---

Russell Miller (CUNY)  Completeness for Fields  BIRS 2013  9 / 17
Corollary

For every countable structure $\mathcal{A}$ which is not automorphically trivial, there exists a field $F$ with the same Turing degree spectrum as $\mathcal{A}$:

$$
\text{Spec}(\mathcal{A}) = \{ \text{deg}(B) : B \cong \mathcal{A} \land \text{dom}(B) = \omega \}
= \{ \text{deg}(E) : E \cong F \land \text{dom}(E) = \omega \}
= \text{Spec}(F).
$$

No infinite field is automorphically trivial, but some infinite structures (including graphs) are, so this case must be excluded.
Consequences: Categoricity Spectra & Dimension

Corollary

For every computable structure $\mathcal{A}$, there exists a computable field $F$ with the same categoricity spectrum as $\mathcal{A}$ and (for each Turing degree $d$) the same $d$-computable dimension as $\mathcal{A}$. Additionally, for every computable ordinal $\alpha$, $F$ is relatively $\Delta^0_\alpha$-categorical if and only if $\mathcal{A}$ is.

That is, for every Turing degree $d$, $\mathcal{A}$ is $d$-computably categorical if and only if $F$ is $d$-computably categorical, and moreover, the number of computable structures isomorphic to $\mathcal{A}$, modulo $d$-computable isomorphism, is exactly the number of computable fields isomorphic to $F$, modulo $d$-computable isomorphism.

In particular, fields realize all computable dimensions $\leq \omega$.

For the relative categoricity claim, recall that every $F' \cong F(G)$ is of the form $F(G')$, up to $F'$-computable isomorphism, with $G' \cong G$. 
Consequences: Computable Categoricity

Downey, Kach, Lempp, Lewis, Montalbán, and Turetsky have recently proven that computable categoricity for trees is $\Pi^1_1$-complete.

**Corollary**

The property of computable categoricity for computable fields is $\Pi^1_1$-complete. That is, the set

$$\{ e \in \omega : \varphi_e \text{ computes a computably categorical field} \}$$

is a $\Pi^1_1$ set, and every $\Pi^1_1$ set is 1-reducible to this set.
The **degree spectrum of a relation** $R$ on a computable structure $\mathcal{A}$ is the set of all Turing degrees of images of $R$ under isomorphisms from $\mathcal{A}$ onto computable structures $\mathcal{B}$.

**Corollary**

Let $\mathcal{A}$ be any computable structure which is not automorphically trivial, and $R$ an $n$-ary relation on $\mathcal{A}$. Then there exists a field $F$ and an $n$-ary relation $S$ on $F$ such that

$$\text{DgSp}_{\mathcal{A}}(R) = \text{DgSp}_F(S).$$
Consequences: Automorphism Spectra

The \textit{automorphism spectrum} of a computable structure $\mathcal{A}$ is the set of all Turing degrees of nontrivial automorphisms of $\mathcal{A}$. This was the subject of study by Harizanov/M/Morozov.

**Corollary**

For every computable structure $\mathcal{A}$, there is a computable field $F$ with the same automorphism spectrum as $\mathcal{A}$. 

Russell Miller (CUNY)
Comparison with Algebraic Fields

In general, algebraic fields hold far less complexity than fields in general.

- For algebraic fields, computable categoricity is a $\Pi^0_4$-complete property (Hirschfeldt-Kramer-M-Shlapentokh), not $\Pi^1_1$.
- Every algebraic field is $0''$-categorical (and better!). Hence many categoricity spectra cannot be realized by computable algebraic fields.
- Likewise, algebraic fields have far simpler spectra (Frolov-Kalimullin-M). The spectrum of an algebraic field $F$ is defined by the ability to enumerate $\{p \in \mathbb{Q}[X] : p \text{ has a root in } F\}$.
- The question of finite computable dimension $> 1$ for algebraic fields remains open.
Zeroing In on $\mathbb{F}(G)$

Every field $\mathbb{F}(G)$ can compute an order on itself. We define a field embedding $h$ of $\mathbb{F}(G)$ into the computable real numbers, effectively.

- $p(7, -10) < 0$, so choose a countable, algebraically independent, uniformly computable set of reals near $-10$, to be the images $h(v_i)$, with all $p(7, h(v_i)) < 0$.
- Then we may choose $h(u_i) > 7$ in $\mathbb{R}$ with $p(h(u_i), h(v_i)) = 0$.
- We need $q(t_{ij}, h(x_{ij}), h(y_{ij})) = 0$, with either $t_{ij} = h(u_i + u_j)$ or $t_{ij} = h(u_i u_j)$. With $t_{ij} > 14$, we know $q(t_{ij}, 0, -\frac{3\sqrt{t_{ij}}}{3/4}) < 0$, so we can choose the $h(y_{ij})$ all algebraically independent, uniformly computable, and close enough to $-\frac{3\sqrt{t_{ij}}}{3/4}$ that $q(t_{ij}, 0, h(y_{ij})) < 0$.
- This allows us to choose $h(x_{ij})$ to be a real root of $q(t_{ij}, X, h(y_{ij}))$. 

But the isomorphisms $\mathbb{F}(G)$ generally do not respect these orderings! Indeed, the archimedean ordered fields are not complete for isomorphisms, by results of Oscar Levin.
Zeroing In on $\mathbb{F}(G)$

Every field $\mathbb{F}(G)$ can compute an order on itself. We define a field embedding $h$ of $\mathbb{F}(G)$ into the computable real numbers, effectively.

- $p(7, -10) < 0$, so choose a countable, algebraically independent, uniformly computable set of reals near $-10$, to be the images $h(v_i)$, with all $p(7, h(v_i)) < 0$.
- Then we may choose $h(u_i) > 7$ in $\mathbb{R}$ with $p(h(u_i), h(v_i)) = 0$.
